

Autofeather – User Manual

This app is used to automatically cause the Photoshop application to iterate over all the images in a directory, and create new versions of them with a feathered/faded frame.

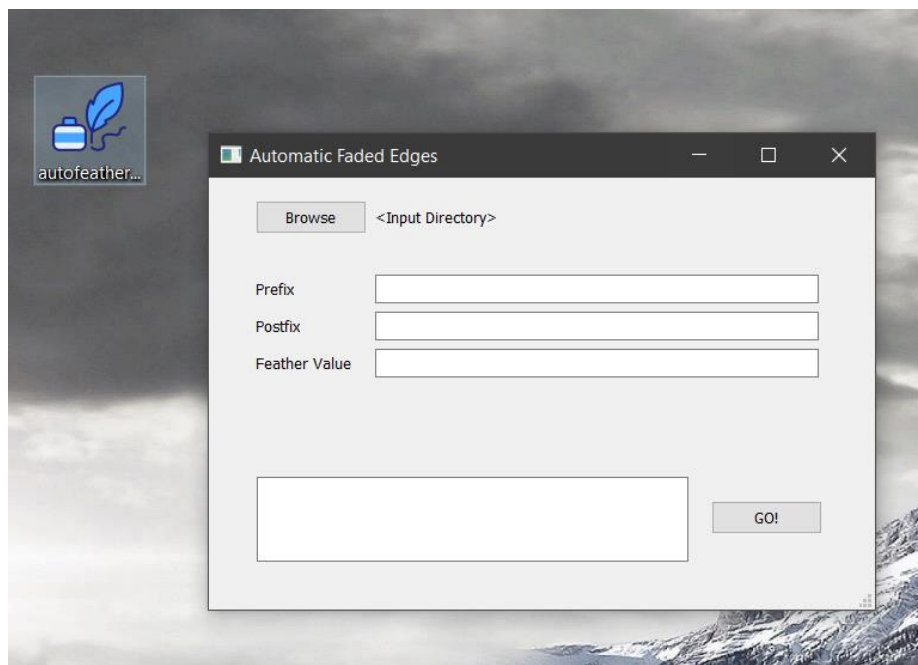

Instructions:

1. Have a directory ready with all the images you want to create feathered duplicates of:

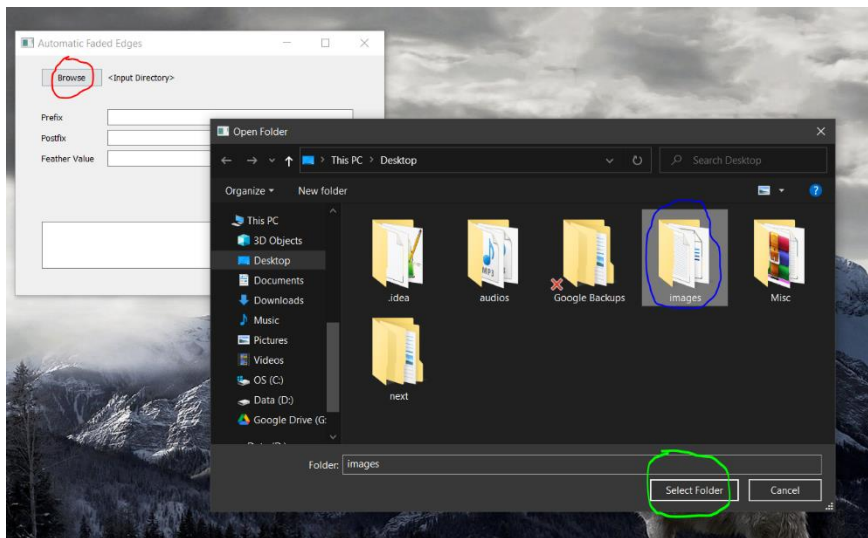

The app will ignore any subdirectories or non-image files.

2. Open the app:

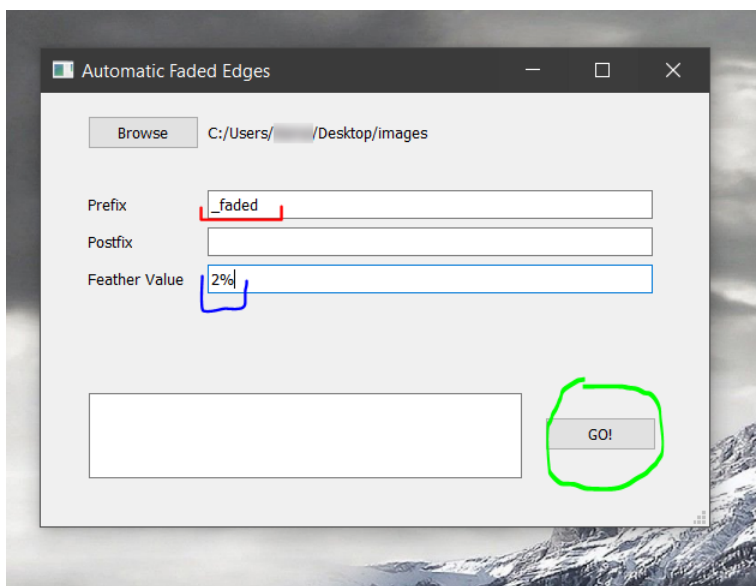

- Click the **Browse** button and locate the folder with your images, then click **select folder**:

- Open Photoshop.** The Photoshop app must be open in the background for the script to automate it and feather your images.
- Add a **prefix**, postfix or both to determine the new image file names. Since the new images are created in the same folder as the old, they cannot have the same name.

Then choose the **feather value**. If written as a number, say 10, it will feather each image 10 pixels from outside in. If written with a % sign, say 2%, it will feather each image a number of pixels equal to 2% of its smaller dimension (better choice if you want faded edges of the same proportion across images of varying sizes, recommended percentages are between 1 and 3).

When done, click the **go** button:

6. Wait until the process is done. The Photoshop app will go through all the steps automatically. After the app is finished, the prompt text box will show the message “DONE”, and the new images will be ready:
